

1. The first step is to identify the problem. This involves understanding the current situation and what needs to be changed.

FIELD AND BACKGROUND OF THE INVENTION

It has long been known, for instance from European patent specifications 0 404 264 and 0 628 357, starting from digital data that define a document, to control not only a printer, but also a processing device for processing printed material into mail pieces.

There is a tendency that more and more possibilities of finishing
25 printed documents are being created. The variety of wishes on the part of
users of such systems then increases accordingly. The origin of address data
which are to be printed on an envelope can, for instance, differ from one
user to another, depending on applications and sources of data used by those

defines at least one document to be printed, a processor for processing the rough print file in accordance with processing instructions into a processed print file, an output interface connected with the printer and with the processing device for transmitting control signals to at least the printer or
5 the processing device for controlling the printer and the processing device in accordance with, or formed by, the processed print file, and memory containing: processing code for controlling the control unit for processing the rough print file into a processed print file, which processing code comprises processing instructions; and representation code for causing the processing
10 instructions to be represented in humanly perceptible form, the representation code being editable for changing at least the representations of the processing instructions, and the representation code being convertible into the processing code.

In the memory of the system, instead of, or supplemental to, the
15 representation code, also a number of processing subroutines can be present, with which the humanly perceptible and editable representation code can be generated.

The invention can further be embodied in computer program code for operating a control unit for controlling a printer and a processing device for
20 processing printed postal items into mail pieces, comprising: processing code for controlling the control unit for processing a rough print file for controlling a printer into a processed print file for controlling the printer and the processing device for processing printed postal items into mail pieces, which processing code comprises processing instructions; and
25 representation code for causing the processing instructions to be represented in humanly perceptible form, the representation code being editable for changing at least the representations of the processing instructions, and the representation code being convertible into the processing code. The computer program code, too, can, instead of or
30 supplemental to the representation code, include a number of processing

subroutines with which the humanly perceptible and editable representation code can be generated.

As representation code is provided for the processing instructions of the processing code to be represented, by equipment suitable therefor, in a humanly perceptible form and flexibly editable as desired, the possibility is obtained not only of setting parameter values but also, for instance, of defining the processing code as regards variables and in particular parameters as well as processing operations in accordance with a large variety of requirements. The flexibility thereby obtained makes it redundant to priorly include a large number of variables and processing operations that can be included in the processing code and further makes redundant a complex user interface, which must be prepared for a large variety of priorly included possibilities.

For that matter, it may be advantageous to include, by standard procedure, a basic set of frequently used parameters in the processing code, and to make these settable in the usual manner, so that for current settings, specifying parameter values can be executed by the user in a simple manner accessible to a broad group of users.

Particularly advantageous embodiments of the invention are laid down in the depending claims.

In the following, the invention is described on the basis of a most preferred exemplary embodiment, and a few variants, with reference to the drawing.

BRIEF DESCRIPTION OF THE DRAWING

Fig. 1 is a schematic representation of a system according to the invention, and

Fig. 2 is a schematic representation of computer software according to the invention.

DETAILED DESCRIPTION

The system represented in Fig. 1 and the structure of the software described hereinafter presently constitute the most preferred exemplary
 5 embodiments of the invention. The system according to Fig. 1 is made up of a printer 1 for printing postal items, a processing device 2 for processing printed postal items into mail pieces; and a control unit 3 for controlling the printer 1 and the processing device 2.

10 The printer is provided with a printer control 4 for controlling the print engine and the supply, feed-through and delivery functions of the printer in accordance with control instructions received from the control unit 3. The processing device 2 according to this example is made up of an inserter station 5 for enveloping documents in envelopes, and an assembly,
 15 located upstream of the inserter station 5, consisting of a transport unit 6 which carries two insert feeder stations 7, 8 and a folding station 9. The inserter station 5 is provided with a processing control unit 10 for controlling the processing of documents by the inserter station 5 and by the stations 7-9 on the transport unit 6 in accordance with control instructions
 20 received from the control unit 3. The processing control unit 10 is connected with a control unit 11 of the transport unit 6 which communicates with control units 12, 13, 14 of the stations 7-9. The control units 10-14 of the processing device 2 are arranged for distributing, in accordance with the processing instructions coming from the control unit 3, processing
 25 instructions and sequence information to the control units 10 and 12-14 of the stations, so that the correct processing operations are executed on the correct documents.

The control unit 3 is provided with an interface 15 coupled to a network 36 for inputting a rough print file for controlling a printer. This
 30 print file, in the form in which it is supplied, does not need to be suitable to

control the printer 1 directly, but does contain data which at least partly define one or more documents to be printed. The control unit 3 is further provided with a processor 16 for processing the rough print file in accordance with processing instructions into a processed print file, and an interface 17 connected with the printer 1 and with the processing device 2 for transmitting control signals to the printer 1 and the processing device in accordance with the processed print file.

The control signals can also be formed by the processed print file which, instead of being sent directly to the printer and to the processing unit, is sent to the printer or the processing unit, whereafter at least the instructions for the other one of the printer and the processing device are forwarded thereto. This last can be done, for instance, in the form of electronic or optical signals, but in particular instructions for the processing unit can also be passed on in the form of printed signs on the documents themselves or on separate items which contain only control information and are not included in mail pieces to be composed. It is also possible for the control signals to be sent in the form of, or in a form corresponding to, the processed print file, to an intermediate station which divides same into separate control signals for the printer and for the processing unit.

It is noted that the precise configuration of the processing unit will naturally vary depending on the application. The number of insert feeder stations, for instance, can be greater if it is desired to include a larger variety of inserts in a series of mail pieces. Further, there may be provided, for instance, a reading station, an accumulation station, an envelope printer, a franking machine, etc.

The control unit 3 further includes a memory in the form of a hard disk on which software has been installed and working memory of the processor 16. Contained in the memory is processing code 19 (see Fig. 2) for controlling the control unit 3 for processing the rough print file 20 into a processed print file 21. Further contained in the memory 18 is

representation code 22-25 for causing the processing instructions to be represented in humanly perceptible form. This representation code is editable for changing the representations of the processing instructions and is convertible into processing code 19 by means of a conversion operation 26.

5 The representation code can, for instance, be stored after the processing code has been taken from it through compilation. It is also possible to provide that the processing code arises only in operation through interpretation and temporarily exists in the form of the instructions with which the processor 16 is controlled at the moment when the processing
10 instructions are executed directly by an interpreter. Hybrid systems, as known per se, can also be used.

 The representation codes 23-25 according to the present example form part of a file 26 and each form a set of instructions in the form of a script. These scripts each form a job setting, i.e. a combination of instructions
15 applying to the assembly of a series of mail pieces. By means of selection code 27, a window with options is presented to a user on a display in the form of a viewing screen 28 (Fig. 1) which is connected with the control unit 3. After a user (this is generally not the person who has composed the scripts) has entered a choice via a keyboard 35, the selected script, in this
20 case script no. 3, is processed by the converter 19 into active processing code 19 with which the processes "parameter preparation" 28 and "processing and transformations" 29 are controlled.

 The processing phase "parameter preparation" 28 concerns processing the rough printing instructions 20 in accordance with the processing
25 instructions 19 into a set of printing instructions 30 with prepared parameters. Parameters according to the script can be, for instance: "supplement inserts" with the contemplated number of sheets being "3". During the processing phase "parameter preparation" 28, from the printing instructions, the number of sheets is determined and for each set of items
30 intended for a mail piece it is filled in by way of parameter values whether

for that set a first insert and a second insert are to be supplied. A further example is that during the parameter preparation for each document the address data to be printed on an envelope are retrieved from a database and for each document are included as a parameter value in the intermediate
5 file 30.

During the processing phase "processing and transformations", the intermediate file 30 is further processed into a file which indicates for each specimen of the mail pieces to be assembled from which of the insert feeding stations 7, 8 inserts are to be supplied, or not. During this phase,
10 transformations can take place as well. Thus, the order of the mail items in the file 30 can be changed, for instance on the basis of address data obtained from the documents, to obtain a sorting which makes it possible to present the mail pieces in pre-sorted condition to, for instance, the postal services. Another sorting possibility, for instance, is one whereby first, mail pieces
15 that can be provided with a first franking are assembled, and then mail pieces that require a different franking are assembled. Further, it is possible to make use of external services 31, for instance to verify address data or to send data regarding mail pieces to be assembled for, for instance, overseas destinations, to an overseas processing unit.

The processing code is obtained according to the present example by processing a script code 22 being processed. In order to make this possible in a simple manner, there is provided a code generator 32 for generating the representation code 22. This code generator constitutes a setting dialog code 32 which presents a user interface with options from predetermined subsets
25 of processing instructions and which offers the possibility of filling in parameter values. These subsets are stored as basic components in a file 33 and, in response to choices entered with the aid of the user interface of the setting dialog 32, are included in the script code being processed 22. The file 33 provides a set of processing subroutines with which representation codes
30 for causing the processing instructions to be represented in humanly

perceptible form can be composed which differ from each other at least as regards processing instructions included therein and which are each convertible to a processing code corresponding with that representation code for controlling the control unit 3 to process the rough print file 20 into a processed print file 21. As a result, the software for the processing code 19
5 can be limited to those processing subroutines that are needed for the respective application and parts that are not necessary can be left out. It may then be advantageous for standard subroutines that occur very frequently to be fixedly included in the processing code.

10 The file of basic components 33 is also consulted during conversion of a script by the converter 26 in response to references, found in the script, to basic components in that file 33. The basic components can also include instructions in the form of parts of script, in which case in response to selection of those basic components those parts of script are included in the
15 script code being processed 22. For executing the processing operations according to those parts of script, the converter does not need to consult the file 33 with basic components.

When the settings that can be set via the setting dialog 32 have been set, the script code being processed 22 can be shown and edited with the aid
20 of script editing code 34. The script editing code 34 is preferably a word processor with provisions for the shortened input and check of script, but also a word editing program can be used as script editing code 34. Next, with the aid of the script, processing operations can be added which cannot be obtained by means of the setting dialog 32. In particular, processing
25 instructions and in particular variables, including formal parameters, are represented and it is made possible to edit these in order to enter other variables, including other formal parameters, to change processing operations and to enter new processing operations.

When a script code being processed 22 is ready, it can be stored as part of the file 26 from which a script can be selected in accordance with which the processing of a print file is to be executed.

Although according to the present example the representation code
5 contains the processing instructions in a script language, it can also be drafted in a different source language such as C, C++, Pascal or, for instance, a fourth-generation language for production planning. However, the use of a script language provides the advantage that desired processing operations can be specified rapidly and flexibly.

10 The converter code 26 can form part of the software belonging to the system or form part of standard software present. It is also possible to have the conversion carried out elsewhere, after which the processing code is returned in a form executable by the control unit and stored, for instance in association with the representation code, to document the content of the
15 processing code. However, the presence of a converter on the system provides the advantage that instructions in the form of representation code can be carried out directly and stepwise, without first requiring a formal intermediate step of complete conversion.

The system proposed can not only be applied in complete systems, but
20 can also be supplied in the form of computer software which is suitable for application for controlling existing systems.

In the following, an example is represented of a script in "Visual Basic Script", the purpose of which part is to supplement addresses and to send all addressees in Amsterdam an insert "Tulip".

25 The print file consists of letters which can be printed on a page. The letters are to be folded in the shape of a Z and to be inserted in a C5/6 window envelope. The text behind a ' sign is an explanation. This script is an example of a representation code such as the scripts 22-25 in Fig. 2.

```

Sub ApplyJob(aPrintFile, aMAILFile)
  ' aPrintFile is the name of the print file 20
  ' aMAILFile is the name of the processed print file 21

5   ' Declaration of variables
    Dim MailSet
    Dim MAILFile
    Dim PrintFile
    Dim Page
10   Dim PageNo
    Dim Company
    Dim Attn
    Dim Street
    Dim City
15   Dim Country

    ' Retrieve the print file 20
    Set PrintFile = CreateObject("ApplyJob.PrintFile")
    PrintFile.LoadPages (aPrintFile)
20

    ' Create the processed print file 21
    Set MAILFile = CreateObject("ApplyJob.MAILFile")

    ' Start with the first page
25   PageNo = 1

    ' Process all pages in the file
    While PageNo <= PrintFile.PageCount

30       ' Add a new mail piece
        Set MailSet = MAILFile.MailSets.Add()

        ' Add the page to the mail piece
        Set Page = MailSet.Pages.Add()
35

        ' Read the printing instructions of the page
        Page.FilePath = PrintFile.PageFilePath(PageNo)

        ' Extract text from a particular position of the page being processed
40       Company = GetWindowText(PrintFile, PageNo, 95, 258, 200, 263)
        Attn = GetWindowText(PrintFile, PageNo, 95, 253, 200, 258)
        Street = GetWindowText(PrintFile, PageNo, 95, 248, 200, 253)
        City = GetWindowText(PrintFile, PageNo, 95, 243, 200, 248)
        Country = GetWindowText(PrintFile, PageNo, 95, 238, 200, 243)
45

        ' Add address information to the mail piece
        MailSet.Attributes.Add ("Company Name")

```

```

MailSet.Attributes.Item("Company Name").Value = Company
MailSet.Attributes.Add ("Attn")
MailSet.Attributes.Item("Attn").Value = Attn
5 MailSet.Attributes.Add ("Street")
MailSet.Attributes.Item("Street").Value = Street
MailSet.Attributes.Add ("City")
MailSet.Attributes.Item("City").Value = City
MailSet.Attributes.Add ("Country")
10 MailSet.Attributes.Item("Country").Value = Country

' Add an insert if address is in Amsterdam
If (City = "Amsterdam") Then
    MailSet.Inserts.Add ("Tulip")
End If

15 ' Specify envelope
MailSet.Envelope = "C5/6 windowed"

' Specify fold
20 MailSet.Fold = "Z-fold"

' Continue with next page
PageNo = pageNo + 1

25 Wend
' All pages have been processed

' Store processed print file 21
MAILFile.Save (aMAILFile)
30 ' Ready
    End Sub

```

35 The processed print file has now been adapted for controlling the
 printer 1 and the processing device 2. In a very simple manner, this script
 can be changed, for instance for adding an algorithm which determines the
 postcode with the aid of an external file and adds it and then an algorithm
 which on the basis of any desired selection from and/or ordering of the
 postcodes, carries out processing operations on the print file.
